Content

1. Terminology
2. Motivation
3. STL Algorithms

2.1. Terminology

Terminology

Standard Library:

The *Standard Library* is the official collection of classes and functions described in and provided with the C++ standard. In parts, the STL is a subset of the Standard Library.

Standard Template Library (STL):

The *STL* is a template-based C++ library developed in the 80s and 90s by Dave Musser, Alexander Stepanov and Meng Lee. Many concepts, ideas, classes, etc., were introduced into the C++ standard library.

2.2. Motivation

The Expert's View on the STL

"There was never any question that the [standard template] library represented a breakthrough in efficient and extensible design."

(Scott Meyers, Effective STL)

The Expert's Advice

"If you want to improve code quality in your organization, I would say, take all your coding guidelines and replace them with the one goal. That's how important I think this one goal is: No Raw Loops. This will make the biggest change in code quality within your organization."

(Sean Parent, C++ Seasoning, Going Native 2013)

2.3. STL Algorithms

STL Algorithms

- Free functions, not member functions
- Operate on half open ranges
- Algorithms are decoupled from containers
- Provide an intuitive naming and parameter convention

```
template< class RandomIt >
void sort( RandomIt first, RandomIt last );

template< class InputIt, class OutputIt >
OutputIt copy( InputIt first, InputIt last, OutputIt d_first );

template< class InputIt, class UnaryPredicate >
InputIt find_if( InputIt first, InputIt last, UnaryPredicate p );
```

Examples

- Copy from a vector to a deque

```
copy( vec.begin(), vec.end(), deq.begin() );
```

- Sort the elements in a vector

```
sort( vec.begin(), vec.end() );
```

- Reverse the order of elements

```
reverse( vec.begin(), vec.end() );
```

- Find the value 5 in a list

```
find( lst.begin(), lst.end(), 5 );
```

Examples

- Copy from a vector of integers to std::cout

```
copy( vec.begin(), vec.end()
    , std::ostream_iterator<int>( std::cout, "\n" ) );
```

- Removing all duplicates from a range

```
sort( vec.begin(), vec.end() );
vec.erase( unique( vec.begin(), vec.end() ), vec.end() );
```

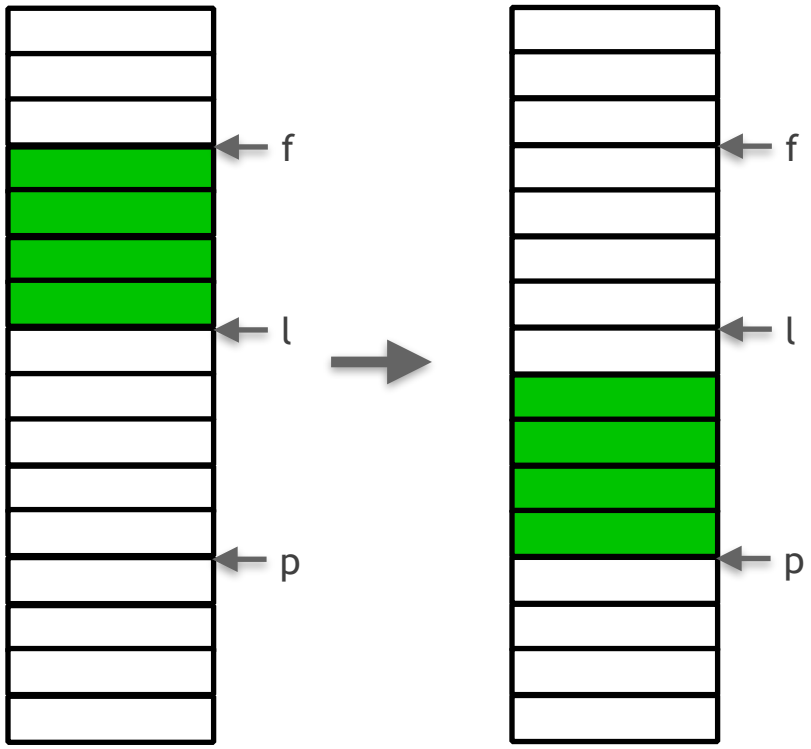
- Find the first odd integer in a list

```
struct IsOdd {
   bool operator()( int i ) const { return i & 0x1; }
};

find_if( lst.begin(), lst.end(), IsOdd() );
```

Examples

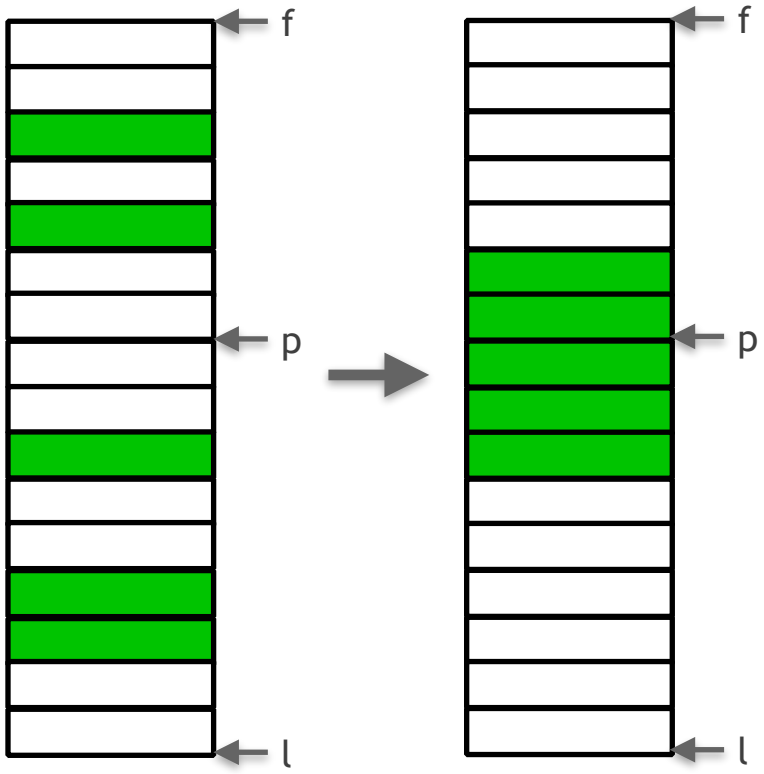
- Move a number of consecutive elements in a vector



```
rotate( f, l, p );
```

Examples

- Gather an arbitrary number of element at a specific position



```
stable_partition(f, p, not1(s));
stable_partition(p, l, s);
```

Programming Task

Task (2_STL_Algorithms/STLintro): Solve the following tasks on a vector of integers by means of STL algorithms:

- Print the contents of the vector to the screen
- Reverse the order of elements in the vector
- Find the first element with the value 5
- Count the elements with the value 5
- Replace all 5s by 2s
- Sort the vector
- Determine the range of 2s

Hint: Use either of the following two web pages as reference.

www.cppreference.com

www.cplusplus.com

Programming Task

Task (2_STL_Algorithms/STLpro): Solve the following tasks on a vector of integers by means of STL algorithms:

- Compute the product of all elements in the vector
- Extract all numbers <= 5 from the vector
- Compute the (numerical) length of the vector
- Compute the ratios v[i+1]/v[i] for all elements v[i] in v
- Move the range [v[3], v[5]] to the beginning of the vector

Hint: Use either of the following two web pages as reference.

www.cppreference.com

www.cplusplus.com

Programming Task

Task (2_STL_Algorithms/Simpson): Implement the empty functions to perform the following operations on the Simpson characters:

- Print all characters to the screen
- Randomize their order
- Find the youngest character
- Order them by first name
- Order them by last name without affecting the order of first names
- Order them by age without affecting the order of first and last names
- Put all Simpsons first without affecting the general order of characters
- Compute the total age of all characters
- Determine the third oldest character as quickly as possible

Programming Task

Task (2_STL_Algorithms/SimpsonPro): Implement the empty functions to perform the following operations on the Simpson characters:

- Print all characters to the screen
- Randomize their order
- Find the youngest character
- Order them by last name without affecting the order of first names
- Highlight the last name of all persons with the given name
- Put all children first
- Compute the total length of all last names
- Check if two adjacent characters have the same age
- Compute the maximum age difference between two adjacent characters
- Determine the median age of all characters

Programming Task

Task (2_STL_Algorithms/Accumulate):

Step 1: Implement the `accumulate()` algorithm. The algorithm should take a pair of iterators, an initial value for the reduction operation, and a binary operation that performs the elementwise reduction.

Step 2: Implement an overload of the `accumulate()` algorithm that uses `std::plus` as the default binary operation.

Step 3: Implement an overload of the `accumulate()` algorithm that uses the default of the underlying data type as initial value and `std::plus` as the default binary operation.

Step 4: Test your implementation with a custom binary operation (e.g. `Times`).

Programming Task

Task (2_STL_Algorithms/SortSubrange): Implement the `sort_subrange()` algorithm in the following example. The algorithm should take four iterators, which specify the total range of elements and the subrange to be sorted.

Programming Task

Task (2_STL_Algorithms/ExtractStrings): Implement the `extract_strings()` algorithm. The algorithm should extract all strings from a long string of space-separated words.

Programming Task

Task (2_STL_Algorithms/LongestStreak): Determine the longest streak of consecutive equal values in the given range of elements.

Programming Task

Task (2_STL_Algorithms/IsPalindrome):

Step 1: Implement the `is_palindrome()` algorithm in the following example. The algorithm should detect if the given range is the same when traversed forward and backward. The algorithm should return `true` only for true palindromes, and `false` for empty ranges and non-palindromes.

Step 2: Restrict the algorithm to bidirectional iterators by means of C++20 concepts.

Algorithm Guidelines

Guideline: “No raw loops” (Sean Parent)

Guideline: “Prefer to use algorithms or embed your raw loop in named functions” (Klaus Iglberger)

Guideline: Use algorithms to reduce duplication (DRY).

Guideline: Know the standard algorithms. They can handle all basic tasks elegantly and efficiently (zero cost abstraction).

Guideline: Use the right algorithm for the right task.

Algorithm Guidelines

Guideline: Consider the design of the STL: It follows SRP, OCP, DRY and builds on the Command design pattern.

Core Guideline P.3: Express intent

Core Guideline T.40: Use function objects to pass operations to algorithms

Core Guideline T.141: Use an unnamed lambda if you need a simple function object in one place only

Limitations of STL Algorithms

Limitations of STL Algorithms - Example 1

Task (2_STL_Algorithms/BadCopy): Explain the error in the following program.

```
vector<int> vec;
list<int> lst;

// ... Initialization of lst

copy( lst.begin(), lst.end(), vec.begin() );
```

- copy() assumes that the target holds enough elements for all elements to be copied
- Reasonable assumption since it is not possible to change the size of a container via the given iterators
- In case the target vector is empty, we enter the realm of undefined behavior

Limitations of STL Algorithms - Example 1

Either resize the `vector` accordingly ...

```
vector<int> vec;
list<int> lst;

// ... Initialization of lst

vec.resize( lst.size() );
copy( lst.begin(), lst.end(), vec.begin() );
```

Limitations of STL Algorithms - Example 1

... or use the following approach:

```
vector<int> vec;
list<int> lst;

// ... Initialization of lst

copy( lst.begin(), lst.end(), std::back_inserter( vec ) );
```

Limitations of STL Algorithms - Example 2

Task (2_STL_Algorithms/BadTransform): Explain the error in the following program.

```
int transmogrify( int x );

vector<int> values;
// ... Put data into the vector

vector<int> results;

// Apply 'transmogrify' to each object in values,
// appending the return values to results
transform( values.begin(), values.end(),
           results.end(), transmogrify );
```

Same problem as in the previous task: The target `vector` has not enough elements → undefined behavior.

Limitations of STL Algorithms - Example 2

Task (continued): Ok, now that we have repaired the access violation, there is an easy way to considerably improve performance. Show how this can be achieved.

```
int transmogrify( int x );

vector<int> values;
// ... Put data into the vector

vector<int> results;

// Apply 'transmogrify()' to each object in values,
// appending the return values to results
transform( values.begin(), values.end(),
           std::back_inserter( results ), transmogrify );
```

Limitations of STL Algorithms - Example 2

If we turn the transmogrify function into a functor, the compiler can take advantage of the inline function definition and inline the function call. This is **not** possible in case of a function pointer.

```
struct Transmogrify {
   inline int operator()( int x ) const { return x * x; }
};

vector<int> values;
// ... Put data into the vector

vector<int> results;

// Apply 'Transmogrify' to each object in values,
// appending the return values to results
transform( values.begin(), values.end(),
           std::back_inserter( results ), Transmogrify() );
```

Limitations of STL Algorithms - Example 2

Core Guideline T.40: Use function objects to pass operations to algorithms

Limitations of STL Algorithms - Example 3

Task (2_STL_Algorithms/BadAccumulate): Explain the error in the following program:

```
vector<double> vec;

// ... Adding elements to vec

const double sum = accumulate( vec.begin(), vec.end(), 0 );
```

- The type of the third parameter defines the type of the accumulator
- adding `double` values to an `int` strips away the floating point part
- the final result is wrong!

Limitations of STL Algorithms - Example 3

Make sure to use the right type for the `init` argument:

```
vector<double> vec;

// ... Adding elements to vec

const double sum =
   accumulate( vec.begin(), vec.end(), double{} );
```

Limitations of STL Algorithms - Example 4

Task (2_STL_Algorithms/BadRemove): Explain the error in the following program:

```
std::vector<int> vec{ 1, -3, 27, 42, 4, -8, 22, 42, 37, 4, 18, 9 };

vec.erase(
   std::remove( begin(vec), end(vec)
              , *std::max_element( begin(vec), end(vec) ) ),
   end(vec) );
```

- `std::remove()` takes its third argument by reference
- passing a reference to the value to be removed may result in aliasing effects
- In case of aliasing final result may be wrong!

Limitations of STL Algorithms - Example 4

Make sure to evaluate the the value in case there is aliasing:

```
std::vector<int> vec{ 1, -3, 27, 42, 4, -8, 22, 42, 37, 4, 18, 9 };

vec.erase(
   std::remove( begin(vec), end(vec)
              , int{ *std::max_element( begin(vec), end(vec) ) } ),
   end(vec) );
```

Things to Remember

- Understand the importance of concepts
- Familiarize yourself with the STL and STL-style code
- Prefer algorithms over handwritten loops
